M5StickC Emergency

The goal of my project was to set up an emergency system that would notify emergency contacts or in this case a discord channel if a person took a heavy fall. This system is geared towards the elderly because they are at higher risk for falls. When a fall is detected using the accelerometer or the m5 button the m5stickC plays an ambulance tone and the screen flashes red and white with a message on it. Then a message is sent to a discord server which is full of family and friends who are notified about the call so that help can be dispatched and delivered quickly. Time is super important when dangerous falls take place, My code is structured as such. At the top are my libraries. I have the m5stickC Plus library. There is also the wifi library and the HTTP client library. Next are my wifi credentials. Then we define the buzzer pin. Next, the m5stickC plus is initialized. Then the wifi is initialized. We then initialize the accelerometer and set the buzzer pin as an output. We then update the m5stickC state. We then get the accelerometer data. We then check if the button was pressed or if a fall was detected. If there was an emergency alert it gets sent out. An ambulance style tone is played and a white and red screen with text is flashed on screen for three seconds.
